In geometry the orientation, angular position, or attitude of an object such as a line, plane or rigid body is part of the description of how it is placed in the space it occupies. Namely, it is the imaginary rotation that is needed to move the object from a reference placement to its current placement. A rotation may not be enough to reach the current placement.

With hexagonal and rhombohedral lattice systems, it is possible to use the Bravais-Miller system, which uses four indices ($h\ k\ i\ \ell$) that obey the constraint $h + k + i = 0$. Here h , k and ℓ are identical to the corresponding Miller indices, and i is a redundant index. This four-index scheme for labeling planes in a hexagonal lattice makes permutation symmetries apparent.

One of the first steps in understanding motion is familiarization with the description and definition of anatomical planes. Anatomists use the mathematical concept of planes in describing anatomical features and their locations. A plane is a flat surface—real or imaginary—upon which a straight ...

American right hand rule: Looking to the strike direction, the bed dips to the right. In our example, that would fit with 000/45. So, looking to the north, the bed dips to the right, to 090 (east). British right hand rule: The thumb of the right hand indicates the dip direction, and the heel points to the strike direction. So in our example, we would record the orientation as 180/45.

Can you tell me how fast this model goes? Unfortunately, we cannot estimate speed of our models. Speed is dependent on a large variety of factors, with the key one being engine and prop selection, but also including engine break-in, altitude, humidity, temperature, fuel and plug, assembly accuracy and, of course, pilot skill.
