In linear algebra, the rank of a matrix is the dimension of the vector space generated (or spanned) by its columns. This corresponds to the maximal number of linearly independent columns of .This, in turn, is identical to the dimension of the space spanned by its rows. Rank is thus a measure of the "nondegenerateness" of the system of linear equations and linear transformation encoded by .

When we multiply matrix A with its inverse matrix A-1 we get an identity matrix. You can observe this kind of matrix like a reciprocal number. Meaning, since the reciprocal number of a is 1/a, that means that number*reciprocal number = 1.Here is the same situation, only we are using matrices.

Introduction: In this lesson, the velocity of a particle traveling on a circular path will be examined. Two different perspectives for measuring a particle's motion are its angular velocity and its linear velocity. During this lesson, we will assume that our objects are moving in uniform circular motion, that is, they are moving along a circular path at a constant speed which is neither ...

To summarize, the linear programming method graphical approach is applied to an objective function, given constraint conditions. The maximum (and minimum) values of this function are found at the vertices of the region defined by the constraints. The most difficult part of the problem is to organize the constraints properly into linear inequalities.
